0x00. AirBnB clone - The console

Group project

Python

OOP

 By: Guillaume Weight: 5 Project to be done in teams of 2 people (your team: Emmanuel Adebayo, Opeyemi Opeyemi) Project over - took place from Aug 1, 2022 6:00 AM to Aug 8, 2022 6:00 AM☒ Manual QA review was done by Bamidele Adefolaju on Aug 11, 2022 8:32 AM☒ An auto review will be launched at the deadline

In a nutshell...

- **Contribution:** 100.0%
- **Manual QA review:** 48.0/48 mandatory
- **Auto QA review:** 300.0/302 mandatory & 233.0/233 optional
- **Altogether: 198.86%**
 - Mandatory: 99.43%
 - Optional: 100.0%
 - Contribution: 100.0%
 - Calculation: $100.0\% * (99.43\% + (99.43\% * 100.0\%)) == 198.86\%$

Concepts

For this project, we expect you to look at these concepts:

- Python packages (/concepts/66)
- AirBnB clone (/concepts/74)

(/)

hbnb

Background Context

Welcome to the AirBnB clone project!

Before starting, please read the **AirBnB** concept page.

HBNB project overview

First step: Write a command interpreter to manage your AirBnB objects.

This is the first step towards building your first full web application: the **AirBnB clone**. This first step is very important because you will use what you build during this project with all other following projects: HTML/CSS templating, database storage, API, front-end integration...

Each task is linked and will help you to:

- put in place a parent class (called `BaseModel`) to take care of the initialization, serialization and deserialization of your future instances

- create a simple flow of serialization/deserialization: Instance <-> Dictionary <-> JSON string <-> file
- (/). create all classes used for AirBnB (User , State , City , Place ...) that inherit from BaseModel
- create the first abstracted storage engine of the project: File storage.
- create all unittests to validate all our classes and storage engine

What's a command interpreter?

Do you remember the Shell? It's exactly the same but limited to a specific use-case. In our case, we want to be able to manage the objects of our project:

- Create a new object (ex: a new User or a new Place)
- Retrieve an object from a file, a database etc...
- Do operations on objects (count, compute stats, etc...)
- Update attributes of an object
- Destroy an object

Resources

Read or watch:

- cmd module (/rltoken/8ecCwE6veBmm3Nppw4hz5A)
- **packages** concept page
- uuid module (/rltoken/KfL9Tqwdl69W6ttG6gTPPQ)
- datetime (/rltoken/1d8l3jSKgnYAtA1IZfEDpA)
- unittest module (/rltoken/IIFiMB8UmqBG2CxAOAD3jA)
- args/kwargs (/rltoken/C_a0EKbtvKdMcwlAuSIZng)
- Python test cheatsheet (/rltoken/tgNVrKKzIWgS4df13mQklw)

Learning Objectives

At the end of this project, you are expected to be able to explain to anyone (/rltoken/uV5eZkRZ_XEqYbgPd-OCWw), **without the help of Google**:

General

- How to create a Python package
- How to create a command interpreter in Python using the cmd module
- What is Unit testing and how to implement it in a large project
- How to serialize and deserialize a Class
- How to write and read a JSON file
- How to manage datetime
- What is an UUID
- What is *args and how to use it
- What is **kwargs and how to use it
- How to handle named arguments in a function

Copyright - Plagiarism

- You are tasked to come up with solutions for the tasks below yourself to meet with the above learning objectives.
- You will not be able to meet the objectives of this or any following project by copying and pasting someone else's work.
- You are not allowed to publish any content of this project.
- Any form of plagiarism is strictly forbidden and will result in removal from the program.

Requirements

Python Scripts

- Allowed editors: `vi`, `vim`, `emacs`
- All your files will be interpreted/compiled on Ubuntu 20.04 LTS using python3 (version 3.8.5)
- All your files should end with a new line
- The first line of all your files should be exactly `#!/usr/bin/python3`
- A `README.md` file, at the root of the folder of the project, is mandatory
- Your code should use the `pycodestyle` (version `2.8.*`)
- All your files must be executable
- The length of your files will be tested using `wc`
- All your modules should have a documentation (`python3 -c 'print(__import__("my_module").__doc__)'`)
- All your classes should have a documentation (`python3 -c 'print(__import__("my_module").MyClass.__doc__)'`)
- All your functions (inside and outside a class) should have a documentation (`python3 -c 'print(__import__("my_module").my_function.__doc__)'` and `python3 -c 'print(__import__("my_module").MyClass.my_function.__doc__)'`)
- A documentation is not a simple word, it's a real sentence explaining what's the purpose of the module, class or method (the length of it will be verified)

Python Unit Tests

- Allowed editors: `vi`, `vim`, `emacs`
- All your files should end with a new line
- All your test files should be inside a folder `tests`
- You have to use the `unittest` module (`/rltoken/op1-rQGlw0wwwqNBsn1yaw`)
- All your test files should be python files (extension: `.py`)
- All your test files and folders should start by `test_`
- Your file organization in the `tests` folder should be the same as your project
- e.g., For `models/base_model.py`, unit tests must be in: `tests/test_models/test_base_model.py`
- e.g., For `models/user.py`, unit tests must be in: `tests/test_models/test_user.py`
- All your tests should be executed by using this command: `python3 -m unittest discover tests`
- You can also test file by file by using this command: `python3 -m unittest tests/test_models/test_base_model.py`
- All your modules should have a documentation (`python3 -c 'print(__import__("my_module").__doc__)'`)

- All your classes should have a documentation (`python3 -c (/) 'print(__import__("my_module").MyClass.__doc__)'`)
- All your functions (inside and outside a class) should have a documentation (`python3 -c 'print(__import__("my_module").my_function.__doc__)'` and `python3 -c 'print(__import__("my_module").MyClass.my_function.__doc__)'`)
- We strongly encourage you to work together on test cases, so that you don't miss any edge case

GitHub

There should be one project repository per group. If you clone/fork/whatever a project repository with the same name before the second deadline, you risk a 0% score.

More Info

Execution

Your shell should work like this in interactive mode:

```
$ ./console.py
(hbnb) help

Documented commands (type help <topic>):
=====
EOF  help  quit

(hbnb)
(hbnb)
(hbnb) quit
$
```

But also in non-interactive mode: (like the Shell project in C)

```
$ echo "help" | ./console.py
(hbnb)
```

Documented commands (type help <topic>):

=====

EOF help quit

(hbnb)

\$

\$ cat test_help

help

\$

\$ cat test_help | ./console.py

(hbnb)

Documented commands (type help <topic>):

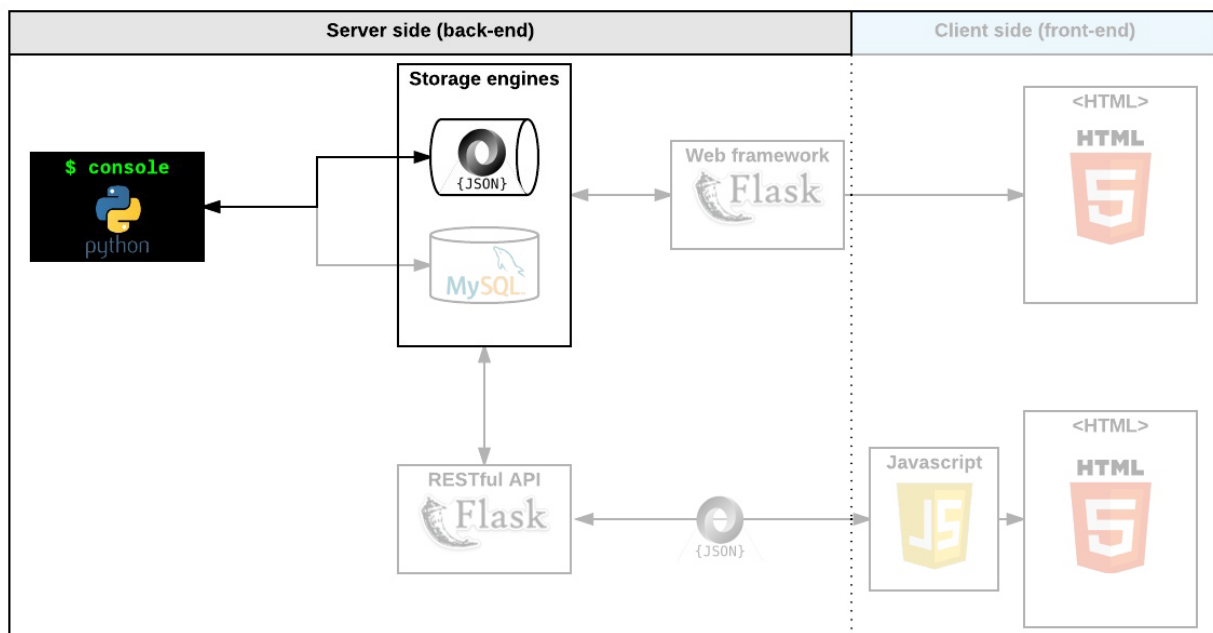

=====

EOF help quit

(hbnb)

\$

All tests should also pass in non-interactive mode: \$ echo "python3 -m unittest discover tests" | bash

(/)

HBNB - The console

Tasks

0. README, AUTHORS

mandatory

Score: 100.00% (Checks completed: 100.00%)

- Write a `README.md` :
 - description of the project
 - description of the command interpreter:
 - how to start it
 - how to use it
 - examples
- You should have an `AUTHORS` file at the root of your repository, listing all individuals having contributed content to the repository. For format, reference Docker's `AUTHORS` page (/rltoken/_8n_z3pf5HWi1I7uv1E9iA)
- You should use branches and pull requests on GitHub - it will help you as team to organize your work

Repo:

- GitHub repository: `AirBnB_clone`
- File: `README.md`, `AUTHORS`

QA Review

2. Unittests

mandatory

Score: 100.00% (Checks completed: 100.00%)

All your files, classes, functions must be tested with unit tests

```
guillaume@ubuntu:~/AirBnB$ python3 -m unittest discover tests
```

```
.....
.....
.....
-----
```

```
Ran 189 tests in 13.135s
```

```
OK
```

```
guillaume@ubuntu:~/AirBnB$
```

Note that this is just an example, the number of tests you create can be different from the above example.

Warning:

Unit tests must also pass in non-interactive mode:

```
guillaume@ubuntu:~/AirBnB$ echo "python3 -m unittest discover tests" | bash
```

```
.....
.....
.....
-----
```

```
Ran 189 tests in 13.135s
```

```
OK
```

```
guillaume@ubuntu:~/AirBnB$
```

3. BaseModel

mandatory

Score: 100.00% (Checks completed: 100.00%)

Write a class `BaseModel` that defines all common attributes/methods for other classes:

- `models/base_model.py`
- Public instance attributes:
 - `id` : string - assign with an `uuid` when an instance is created:
 - you can use `uuid.uuid4()` to generate unique `id` but don't forget to convert to a string
 - the goal is to have unique `id` for each `BaseModel`
 - `created_at` : datetime - assign with the current datetime when an instance is created
 - `updated_at` : datetime - assign with the current datetime when an instance is created and it will be updated every time you change your object
- `__str__` : should print: [`<class name>`] (`<self.id>`) `<self.__dict__>`
- Public instance methods:
 - `save(self)` : updates the public instance attribute `updated_at` with the current datetime
 - `to_dict(self)` : returns a dictionary containing all keys/values of `__dict__` of the instance:
 - by using `self.__dict__`, only instance attributes set will be returned
 - a key `__class__` must be added to this dictionary with the class name of the object
 - `created_at` and `updated_at` must be converted to string object in ISO format:
 - format: `%Y-%m-%dT%H:%M:%S.%f` (ex: `2017-06-14T22:31:03.285259`)
 - you can use `isoformat()` of datetime object
 - This method will be the first piece of the serialization/deserialization process: create a dictionary representation with "simple object type" of our `BaseModel`

```
guillaume@ubuntu:~/AirBnB$ cat test_base_model.py
#!/usr/bin/python3

from models.base_model import BaseModel

my_model = BaseModel()
my_model.name = "My First Model"
my_model.my_number = 89
print(my_model)
my_model.save()
print(my_model)
my_model_json = my_model.to_dict()
print(my_model_json)
print("JSON of my_model:")
for key in my_model_json.keys():
    print("\t{:} ({} - {}".format(key, type(my_model_json[key]), my_model_json[key]))

guillaume@ubuntu:~/AirBnB$ ./test_base_model.py
[BaseModel] (b6a6e15c-c67d-4312-9a75-9d084935e579) {'my_number': 89, 'name': 'My First Model', 'updated_at': datetime.datetime(2017, 9, 28, 21, 5, 54, 119434), 'id': 'b6a6e15c-c67d-4312-9a75-9d084935e579', 'created_at': datetime.datetime(2017, 9, 28, 21, 5, 54, 119427)}

QA Review

4. Create BaseModel from dictionary (/)

Score: 100.00% (Checks completed: 100.00%)

Previously we created a method to generate a dictionary representation of an instance (method `to_dict()`).

Now it's time to re-create an instance with this dictionary representation.

```
<class 'BaseModel'> -> to_dict() -> <class 'dict'> -> <class 'BaseModel'>
```

Update `models/base_model.py`:

- `__init__(self, *args, **kwargs)`:
 - you will use `*args`, `**kwargs` arguments for the constructor of a `BaseModel`. (more information inside the **AirBnB clone** concept page)
 - `*args` won't be used
 - if `kwargs` is not empty:
 - each key of this dictionary is an attribute name (**Note** `__class__` from `kwargs` is the only one that should not be added as an attribute. See the example output, below)
 - each value of this dictionary is the value of this attribute name
 - **Warning:** `created_at` and `updated_at` are strings in this dictionary, but inside your `BaseModel` instance is working with `datetime` object. You have to convert these strings into `datetime` object. Tip: you know the string format of these `datetime`
 - otherwise:
 - create `id` and `created_at` as you did previously (new instance)

```
guillaume@ubuntu:~/AirBnB$ cat test_base_model_dict.py
#!/usr/bin/python3

from models.base_model import BaseModel

my_model = BaseModel()
my_model.name = "My_First_Model"
my_model.my_number = 89
print(my_model.id)
print(my_model)
print(type(my_model.created_at))
print("--")
my_model_json = my_model.to_dict()
print(my_model_json)
print("JSON of my_model:")
for key in my_model_json.keys():
    print("\t{:} ({} - {}".format(key, type(my_model_json[key]), my_model_json[key]))

print("--")
my_new_model = BaseModel(**my_model_json)
print(my_new_model.id)
print(my_new_model)
print(type(my_new_model.created_at))

print("--")
print(my_model is my_new_model)

guillaume@ubuntu:~/AirBnB$ ./test_base_model_dict.py
56d43177-cc5f-4d6c-a0c1-e167f8c27337
[BaseModel] (56d43177-cc5f-4d6c-a0c1-e167f8c27337) {'id': '56d43177-cc5f-4d6c-a0c1-e167f8c27337', 'created_at': datetime.datetime(2017, 9, 28, 21, 3, 54, 52298), 'my_number': 89, 'updated_at': datetime.datetime(2017, 9, 28, 21, 3, 54, 52302), 'name': 'My_First_Model'}

QA Review

5. Store first object

mandatory

Score: 100.00% (Checks completed: 100.00%)

Now we can recreate a `BaseModel` from another one by using a dictionary representation:

```
<class 'BaseModel'> -> to_dict() -> <class 'dict'> -> <class 'BaseModel'>
```

It's great but it's still not persistent: every time you launch the program, you don't restore all objects created before... The first way you will see here is to save these objects to a file.

Writing the dictionary representation to a file won't be relevant:

- Python doesn't know how to convert a string to a dictionary (easily)
- It's not human readable
- Using this file with another program in Python or other language will be hard.

So, you will convert the dictionary representation to a JSON string. JSON is a standard representation of a data structure. With this format, humans can read and all programming languages have a JSON reader and writer.

Now the flow of serialization-deserialization will be:

```
<class 'BaseModel'> -> to_dict() -> <class 'dict'> -> JSON dump -> <class 'str'> ->
FILE -> <class 'str'> -> JSON load -> <class 'dict'> -> <class 'BaseModel'>
```

Magic right?

Terms:

- **simple Python data structure:** Dictionaries, arrays, number and string. ex: `{ '12': { 'numbers': [1, 2, 3], 'name': "John" } }`
- **JSON string representation:** String representing a simple data structure in JSON format. ex: `'{"12": { "numbers": [1, 2, 3], "name": "John" } }'`

Write a class `FileStorage` that serializes instances to a JSON file and deserializes JSON file to instances:

(/)

- `models/engine/file_storage.py`
- Private class attributes:
 - `__file_path` : string - path to the JSON file (ex: `file.json`)
 - `__objects` : dictionary - empty but will store all objects by `<class name>.id` (ex: to store a `BaseModel` object with `id=12121212` , the key will be `BaseModel.12121212`)
- Public instance methods:
 - `all(self)` : returns the dictionary `__objects`
 - `new(self, obj)` : sets in `__objects` the `obj` with key `<obj class name>.id`
 - `save(self)` : serializes `__objects` to the JSON file (path: `__file_path`)
 - `reload(self)` : deserializes the JSON file to `__objects` (only if the JSON file (`__file_path`) exists ; otherwise, do nothing. If the file doesn't exist, no exception should be raised)

Update `models/__init__.py` : to create a unique `FileStorage` instance for your application

- `import file_storage.py`
- create the variable `storage` , an instance of `FileStorage`
- call `reload()` method on this variable

Update `models/base_model.py` : to link your `BaseModel` to `FileStorage` by using the variable `storage`

- import the variable `storage`
- in the method `save(self)` :
 - call `save(self)` method of `storage`
- `__init__(self, *args, **kwargs)` :
 - if it's a new instance (not from a dictionary representation), add a call to the method `new(self)` on `storage`

```
guillaume@ubuntu:~/AirBnB$ cat test_save_reload_base_model.py
#!/usr/bin/python3

from models import storage
from models.base_model import BaseModel

all_objs = storage.all()
print("-- Reloaded objects --")
for obj_id in all_objs.keys():
    obj = all_objs[obj_id]
    print(obj)

print("-- Create a new object --")
my_model = BaseModel()
my_model.name = "My_First_Model"
my_model.my_number = 89
my_model.save()
print(my_model)

guillaume@ubuntu:~/AirBnB$ cat file.json
cat: file.json: No such file or directory
guillaume@ubuntu:~/AirBnB$
guillaume@ubuntu:~/AirBnB$ ./test_save_reload_base_model.py

QA Review

6. Console 0.0.1

mandatory

Score: 100.00% (Checks completed: 100.00%)

Write a program called `console.py` that contains the entry point of the command interpreter:

- You must use the module `cmd`
- Your class definition must be: `class HBNBCommand(cmd.Cmd):`
- Your command interpreter should implement:
 - `quit` and `EOF` to exit the program
 - `help` (this action is provided by default by `cmd` but you should keep it updated and documented as you work through tasks)
 - a custom prompt: `(hbnb)`

- an empty line + ENTER shouldn't execute anything
- (/). Your code should not be executed when imported

**Warning:**

You should end your file with:

```
if __name__ == '__main__':
    HBNBCommand().cmdloop()
```

to make your program executable except when imported. Please don't add anything around - the Checker won't like it otherwise

```
guillaume@ubuntu:~/AirBnB$ ./console.py
(hbnb) help

Documented commands (type help <topic>):
=====
EOF  help  quit

(hbnb)
(hbnb) help quit
Quit command to exit the program

(hbnb)
(hbnb)
(hbnb) quit
guillaume@ubuntu:~/AirBnB$
```

- GitHub repository: AirBnB_clone
- File: console.py

☒ Done!

7. Console 0.1

Score: 100.00% (Checks completed: 100.00%)

Update your command interpreter (console.py) to have these commands:

- create : Creates a new instance of BaseModel , saves it (to the JSON file) and prints the id . Ex: \$ create BaseModel

- (/)
- If the class name is missing, print `** class name missing **` (ex: `$ create`)
 - If the class name doesn't exist, print `** class doesn't exist **` (ex: `$ create MyModel`)
 - `show` : Prints the string representation of an instance based on the class name and `id`. Ex: `$ show BaseModel 1234-1234-1234`.
 - If the class name is missing, print `** class name missing **` (ex: `$ show`)
 - If the class name doesn't exist, print `** class doesn't exist **` (ex: `$ show MyModel`)
 - If the `id` is missing, print `** instance id missing **` (ex: `$ show BaseModel`)
 - If the instance of the class name doesn't exist for the `id`, print `** no instance found **` (ex: `$ show BaseModel 121212`)
 - `destroy` : Deletes an instance based on the class name and `id` (save the change into the JSON file). Ex: `$ destroy BaseModel 1234-1234-1234`.
 - If the class name is missing, print `** class name missing **` (ex: `$ destroy`)
 - If the class name doesn't exist, print `** class doesn't exist **` (ex: `$ destroy MyModel`)
 - If the `id` is missing, print `** instance id missing **` (ex: `$ destroy BaseModel`)
 - If the instance of the class name doesn't exist for the `id`, print `** no instance found **` (ex: `$ destroy BaseModel 121212`)
 - `all` : Prints all string representation of all instances based or not on the class name. Ex: `$ all BaseModel` or `$ all`.
 - The printed result must be a list of strings (like the example below)
 - If the class name doesn't exist, print `** class doesn't exist **` (ex: `$ all MyModel`)
 - `update` : Updates an instance based on the class name and `id` by adding or updating attribute (save the change into the JSON file). Ex: `$ update BaseModel 1234-1234-1234 email "aibnb@mail.com"`.
 - Usage: `update <class name> <id> <attribute name> "<attribute value>"`
 - Only one attribute can be updated at the time
 - You can assume the attribute name is valid (exists for this model)
 - The attribute value must be casted to the attribute type
 - If the class name is missing, print `** class name missing **` (ex: `$ update`)
 - If the class name doesn't exist, print `** class doesn't exist **` (ex: `$ update MyModel`)
 - If the `id` is missing, print `** instance id missing **` (ex: `$ update BaseModel`)
 - If the instance of the class name doesn't exist for the `id`, print `** no instance found **` (ex: `$ update BaseModel 121212`)
 - If the attribute name is missing, print `** attribute name missing **` (ex: `$ update BaseModel existing-id`)
 - If the value for the attribute name doesn't exist, print `** value missing **` (ex: `$ update BaseModel existing-id first_name`)
 - All other arguments should not be used (Ex: `$ update BaseModel 1234-1234-1234 email "aibnb@mail.com" first_name "Betty" = $ update BaseModel 1234-1234-1234 email "aibnb@mail.com"`)
 - `id`, `created_at` and `updated_at` can't be updated. You can assume they won't be passed in the update command
 - Only "simple" arguments can be updated: string, integer and float. You can assume nobody will try to update list of ids or datetime

Let's add some rules:

(/)

- You can assume arguments are always in the right order
- Each arguments are separated by a space
- A string argument with a space must be between double quote
- The error management starts from the first argument to the last one

```
guillaume@ubuntu:~/AirBnB$ ./console.py

QA Review

8. First User

mandatory

Score: 100.00% (*Checks completed: 100.00%*)

Write a class `User` that inherits from `BaseModel` :

- `models/user.py`
- Public class attributes:
 - `email : string` - empty string
 - `password : string` - empty string
 - `first_name : string` - empty string
 - `last_name : string` - empty string

Update `FileStorage` to manage correctly serialization and deserialization of `User` .

Update your command interpreter (`console.py`) to allow `show` , `create` , `destroy` , `update` and all used with `User` .

```
guillaume@ubuntu:~/AirBnB$ cat test_save_reload_user.py
```

```
#!/usr/bin/python3
```

```
from models import storage
from models.base_model import BaseModel
from models.user import User
```

```
all_objs = storage.all()
print("-- Reloaded objects --")
for obj_id in all_objs.keys():
    obj = all_objs[obj_id]
    print(obj)
```

```
print("-- Create a new User --")
my_user = User()
my_user.first_name = "Betty"
my_user.last_name = "Bar"
my_user.email = "airbnb@mail.com"
my_user.password = "root"
my_user.save()
print(my_user)
```

```
print("-- Create a new User 2 --")
my_user2 = User()
my_user2.first_name = "John"
my_user2.email = "airbnb2@mail.com"
my_user2.password = "root"
my_user2.save()
print(my_user2)
```

```

9. More classes!

mandatory

Score: 100.00% (Checks completed: 100.00%)

Write all those classes that inherit from BaseModel :

- State (models/state.py):
 - Public class attributes:
 - name : string - empty string
- City (models/city.py):
 - Public class attributes:
 - state_id : string - empty string: it will be the State.id
 - name : string - empty string
- Amenity (models/amenity.py):
 - Public class attributes:
 - name : string - empty string
- Place (models/place.py):
 - Public class attributes:
 - city_id : string - empty string: it will be the City.id
 - user_id : string - empty string: it will be the User.id
 - name : string - empty string
 - description : string - empty string
 - number_rooms : integer - 0
 - number_bathrooms : integer - 0
 - max_guest : integer - 0
 - price_by_night : integer - 0
 - latitude : float - 0.0
 - longitude : float - 0.0

- `amenity_ids` : list of string - empty list: it will be the list of `Amenity.id` later
- (/). Review (`models/review.py`):

- Public class attributes:
 - `place_id` : string - empty string: it will be the `Place.id`
 - `user_id` : string - empty string: it will be the `User.id`
 - `text` : string - empty string

10. Console 1.0

mandatory

Score: 100.00% (*Checks completed: 100.00%*)

Update `FileStorage` to manage correctly serialization and deserialization of all our new classes: `Place` , `State` , `City` , `Amenity` and `Review`

Update your command interpreter (`console.py`) to allow those actions: `show` , `create` , `destroy` , `update` and `all` with all classes created previously.

Enjoy your first console!

No unittests needed for the console**Repo:**

- GitHub repository: `AirBnB_clone`

17. Unittests for the Console!

#advanced

Score: 100.00% (Checks completed: 100.00%)

Write all unittests for console.py, all features!

For testing the console, you should "intercept" STDOUT of it, we **highly** recommend you to use:

```
with patch('sys.stdout', new=StringIO()) as f:
    HBNBCommand().onecmd("help show")
```

Otherwise, you will have to re-write the console by replacing precmd by default.

Repo:

- GitHub repository: AirBnB_clone

• File: tests/test_console.py
(/)
